MongoDB and PHP

César D. Rodas crodas@ferpectos.com

http://cesarodas.com/

Latinoware 2010 Foz do Iguaçu, Brasil

Who is this fellow?

- Paraguayan :-)
- Zealot of
 - Open Source (BSD-license)
 - PHP
 - MongoDB
- PHP/PECL Developer
- Work for a cool company (btw, we're hiring)
- ... and few other things

Agenda

- Introduction to MongoDB
- MongoDB Queries
- Real life example:
 - Designing data model for a Wordpress.com like site
 - Optimize our data model to run in sharded environment

MongoDB

- <EN>Mongo</EN>!= <PT>Mongo</PT>
- Document oriented database
- Fast, Scalable, Easy to use (devel-friendly)
- Support Indexes
 - Simple
 - Compound
 - Geo spatial
- Schemaless
- Support sharding
- Nested documents
- PECL client

Documents?

It's just an Array()

In fact everything is an Array() in MongoDB

http://bit.ly/mongodb-php

MongoDB - Operations

• Select

- \$gt, \$lt, \$gte, \$lte, \$eq, \$neq: >, <, >=, <=, ==, !=
- \$in, \$nin, \$or
- \$size, \$exists
- \$where: Any javascript expression
- group()
- limit()
- skip()

Update

- \$set
- \$unset
- \$push
- \$pull
- \$inc
- findAndModify()

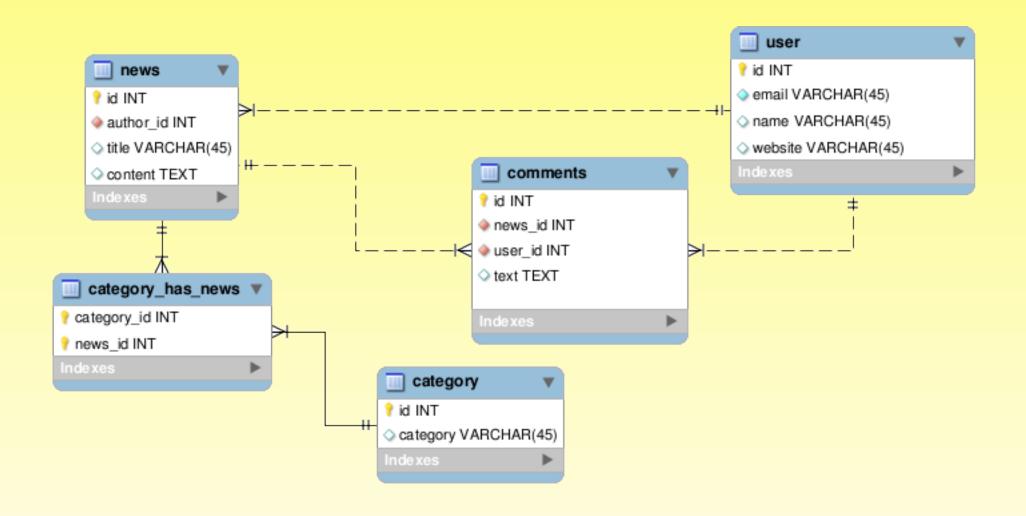

Is it better than MySQL (or Pg)?

NO

It is different.

Differences with a rel. database

- Denormalize data is not bad
 - It makes queries simplest and faster
 - Disk-space is much cheaper than CPU (and your user's time)
 - Much simple to distribute data across multiple nodes
- No CPU wasting doing ORM
 - Objects in the programming language and in the database
 - No abstraction to generate SQL
- No SQL injection :-)
- No Joins (they are evil!)
- Batch processing
- No CREATE TABLE (or ALTER TABLE) needed

The fun part

Data-structure

```
suser = array(
                    'name' => 'crodas',
                    'email' => 'crodas@ferpectos.com',
                    'website' => 'http://cesarodas.com',
category = array(
                    array('name' => 'Sport', 'description' => 'foo'),
                    array('name' => 'Politcs', 'description' => 'bar')
something to the second seco
                    'news' => $news['_id'],
                    'text' => 'I like MongoDB',
                    // these are duplicated!
                    'name' => $user['name'], /* 'crodas' */
                    'website' => $user['website'], /*'http://cesarodas.com',*/
```

```
news = array(
    'title' => 'My Talk about MongoDB',
    'content' => 'MongoDB rules, bla, bla!'
    'author' => $user['_id'],
    // duplicated items
    'authorName' => $user['user'],
    'categories' => array(
        // copy all categories (incuding _id and name)
        \operatorname{array}(\operatorname{'id'} => \operatorname{\$category}[0][\operatorname{'\_id'}], \operatorname{'name'} => \operatorname{\$category}[0][\operatorname{'name'}]),
    'comments' => array(
        // copy 10 comments (we show 10 comments and pagination buttons)
        $comment[0],
        $comment[1],
    // total comments for this news, to made easier pagination
    'totalComments' => count($comment),
```

Select

```
// MySQL
"SELECT news.*, user.name FROM news
INNER JOIN user ON user.id = news.author_id WHERE id = 1"
"SELECT category.category FROM category_has_news
INNER JOIN category ON category WHERE news_id = 1"
"SELECT * FROM comments
INNER JOIN user ON user.id = comments.user_id
WHERE news_id = 1"
// In MongoDB
$mongo = new MongoDB;
db = mongo-database;
news = db->news->find(array('_id' => 1));
```

Select

```
// Get 10-most commented news
$db->news->find(array())->sort(array('totalComments' => -1))->limit(5);

// MySQL
// I'm bored to think in SQL
```

Add new comment

```
query = array('_id' => post['news_id']);
$properties = array('totalComments' => true);
$news = $db->news->findOne($query, $properties);
if (empty($news)) throw new Exception("not valid news");
new_comment = array(
   'name' => $_SESSION['user']['name'],
   'website' => $_SESSION['user']['website'],
   'text' => $_POST['text'], 'news' => $_POST['news_id'],
$db->comment->save($new_comment);
$update = array('\$inc' => array('totalComments' => 1));
if ($news['totalComments'] < 10)
   $update['$push'] = array('comments' => $new_comment);
$db->news->update($news, $update);
```

What if the user changes its name?

Update

// Catch the update event somewhere in your app and run this: update comments $\quad \text{$update = array()}$ '\$set' => array('name' => \$new_name) \$db->comments->update(array('news' => 1), \$update, array('multiple' => true)); // update news (and embed comments) $\quad \text{supdate} = \text{array}($ '\$set' => array('comments' => \$list_of_first_10_comments, 'authorName' => \$new_name, \$db->news->update(array('_id' => 1), \$update, array('multiple' => true));

What about schema migration?

Update Schema

Update Schema

```
// better approach (can run multiple instances safely)
while (true) {
   news = db->command(array(
       'findAndModify' => 'news',
       // where url doesn't exists (much better than $exists => false)
       'query' => array('url' => null),
       // set a new value for url, diff than null
       'update' => array('$set' => 'url' => ''),
   ));
   if (\text{snews}[\text{ok'}] != 1) break;
   query = array('_id') => news['value']['_id']):
   = \operatorname{array}('set' => \operatorname{array}('url' => \operatorname{get\_url\_from\_title}(\operatorname{snews}['value']['title']));
   $db->news->update($query, $update);
```

Beyond SQL!

Store files

- No need of any distributed File system
- Each file has a checksum
- 100% customizable
 - Open data structure
 - You can extend it to support locking
 - You can save as much meta data as you want
- Works in a sharded-environment
- Native extension for NGINX

Store files

```
grid = db-\gcdGridFS();
metadata = array(
   "whatever" => "metadata",
   "path" => "/foo",
   "download" => 0
$grid->storeFile($filename, $metadata);
// or
$grid->storeBytes($bytes, $metadata);
// Or (save $_FILE['foo'])
$grid->storeUpload('foo', $metadata);
```

Read file

```
grid = db-\gcdGridFS();
$file = $grid->findOne(array('path' => '/foo'));
// update download
$update = array('$inc' => array('download' => 1));
d = array('_id') => file->file['_id']);
$grid->update($id, $update);
// print it
echo $file->Bytes();
// or (a bit better)
$tmp = '/tmp/apache/' . $file->file['_id'];
if (!is_file($tmp)) $file->write($tmp);
virtual($tmp);
```

Questions?

Thanks
